Windows of one child
Window 1
Window 2
Window n
electrodes by samples, one label
Front-end features
(1) Circular Data Re-Uploading (CDRU)
repeated L times
Encoding Y rotation of each feature, unit scale
Trainable Z and Y rotations
CNOT ring closed
The same features re-enter every layer, so the number of layers alone fixes the frequencies the circuit can represent
Readout linear logit on the expectations, then sigmoid
Child decision mean window probability
Objective subject-weighted cross-entropy and readout penalty
Diagnosis
Jacobian
output gradient
Map per electrode and sample
(2) Analytical Saliency via Parameter-Shift Backpropagation
Feature attribution exact derivative by parameter shift
Saliency chained through the front-end to each electrode and sample
data flow
supervision
exact gradient
contribution
